

Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact support@jstor.org.

JANUARY 18.

The President, Dr. Ruschenberger, in the chair. Forty-three members present.

JANUARY 25.

The President, Dr. Ruschenberger, in the chair.

Forty-five members present.

The following were elected members: Chas. L. Sharpless, Dr. Alfred Whelen, Rev. W. Q. Scott, Dr. Henry M. Fisher, Edwin H. Fitler, Dr. Wm. R. Cruice, Chas. H. Rogers, and Dr. W. F. Waugh.

FEBRUARY 1.

The President, Dr. Ruschenberger, in the chair.

Forty-six members present.

A paper entitled "Description of a New Generic Type, Bassaricyon Gabbii, of Procyonidæ from Costa Rica," by J. A. Allen was presented for publication.

On a Gigantic Bird from the Eocene of New Mexico.—Prof. Cope exhibited a tarsometatarsus of a bird, discovered by himself during the explorations in New Mexico, conducted by Lieut. G. M. Wheeler, U. S. A. The characters of its proximal extremity resemble in many points those of the order Cursores (represented by the Struthionidæ and Dinornis), while those of the distal end are, in the middle and inner trochleæ, like those of the Gastornis of the Paris Basin. Its size indicates a species with feet twice the bulk of those of the ostrich. The discovery introduces this group of birds to the known faunæ of North America recent and extinct, and demonstrates that this continent has not been destitute of the gigantic forms of birds, heretofore chiefly found in the Southern Hemisphere faunæ. The description is as follows:—

The hypotarsus is moderately prominent, with broad truncate

The hypotarsus is moderately prominent, with broad truncate face, and does not inclose the ligamentous groove of its inner side. Its superior angle is broken away in the specimen. The two foramina which pierce the shaft just below the head, are well separated from each other both on the posterior and anterior faces, marking nearly equal thirds of the transverse diameter of the bone. The

cotyloid cavities for the tibio-tarsus are bounded by an elevated margin, and are separated medially by a single low oblique ridge. The groove of the posterior face is particularly wide, and the inner part of the shaft is thinned, while the outer border is broadly convex. The proximal part of the inner border (as far as it is preserved) is marked with a flat surface which is roughened with ridges, which is perhaps the sutural articulation of the proximal end of the metatarsus of the hallux. No such surface exists on the corresponding bone of the ostrich or emeu. Only two of the free distal phalangeal extremities are preserved. The shaft is broken, showing that its interior is filled with cancellous tissue. The free extremities are remarkable for the great inferior extent of the articular trochlear face. The median is strongly grooved with an obtuse excavation, and the lateral or bordering ridges are equal and rounded. The groove is continuous with the superior surface, but not with the inferior. There the convergent lateral ridges inlosing the open groove, terminate in an abrupt elevation above the adjacent surface of the shaft. The sides at this point are concave. The inner free condyle has an oblique articular face, the external ridge dropping away internally as in many birds, and produced beyond the inner ridge, distally. The articular face becomes then a part of a spiral, and is little grooved above, but strongly grooved medially. The vertical diameters of the sides differ, the inner being much greater, and both are concave. A strong foramen pierces the shaft just within the point of junction of the inner and medial free extremities.

${\it Measurements.}$						М.
Transverse diameter of proximal end of tarsometatarsus .						.100
Antero-posterior do. (partly inferential)						.070
Interval between penetrating foramina on anterior face shaft						.017
_	Long diameter .					.050
Median distal condyle	Vertical diameter .					.048
	Transverse diameter				•	.040
Internal distal condyle	Long diameter .					.037
		•	•	•		.040
	Transverse diameter					.031

The large size and wide separation of the penetrating foramina, and the thin internal edge with sutural articular facet, distinguish this form as distinct from any of the genera of Struthionidæ and Dinornithidæ. It is therefore named Diatryma gigantea.

On Strontianite and Associated Minerals in Mifflin Co.—Mr. Henry Carvill Lewis remarked that it might be of interest to mention the occurrence of Strontianite in Pennsylvania—a mineral which he believed had not been heretofore recorded as occurring in our State.

He had found it quite abundantly in Mifflin County on the Juniata opposite Mount Union. It exists as tufts of white acicular
